5.6 Global Minimum Cut

```

1 #include <./basic/Template.h>
2 /*Given an undirected graph  $G = (V, E)$ , we define a
3 cut of  $G$  to be a partition
4 of  $V$  into two non-empty sets  $A$  and  $B$ . Earlier, when
5 we looked at network
6 flows, we worked with the closely related definition
7 of an s-t cut: there, given
8 a directed graph  $G = (V, E)$  with distinguished source
9 and sink nodes  $s$  and  $t$ ,
10 an s-t cut was defined to be a partition of  $V$  into
11 sets  $A$  and  $B$  such that  $s \in A$ 
12 and  $t \in B$ . Our definition now is slightly different,
13 since the underlying graph
14 is now undirected and there is no source or sink.
15 This problem can be solved by max-flow. First we
16 remove undirected edges and replace
17 them by two opposite directed edge. Now we fix a node
18  $s$ . Then we consider each of
19 the  $n$  nodes as  $t$  and run max-flow. The minimum of
20 those values is the answer.
21 This is  $O(n^3)$ .
